Inspecting the Mechanism of Quantitative Easing in the Euro Area with Ralph S.J. Koijen, François Koulischer & Motohiro Yogo. *Journal of Financial Economics* (Apr 2021).

Using new data on security-level portfolio holdings by investor type and for all countries in the euro area, we study portfolio rebalancing during the European Central Bank's (ECB) purchase programme that started in March 2015. To quantify changes in risk concentration, we estimate the evolution of the distribution of duration, government, and corporate credit risk exposures across investor sectors and regions until the last quarter of 2017. We estimate a sector-level asset demand system using instrumental variables to connect the dynamics of portfolio rebalancing to asset prices. Our estimates imply that government yields declined by 63bp, on average, and the estimates range from -37bp to -77bp across countries.

The Scarcity Effect of Quantitative Easing on Repo Rates: Evidence from the Euro Area with W. Arrata, I. Rahmouni-Rousseau and M. Vari, *Journal of Financial Economics* (Sept 2020).

In this paper, we explore empirically the interactions between the PSPP and repo rates. We document different channels through which asset purchases may affect them. Using proprietary data from PSPP purchases and repo transactions for specific ("special") securities, we assess the scarcity channel of PSPP and its impact on repo rates. We estimate that purchasing 1 percent of a bond outstanding is associated with a decline of its repo rate of 0.78 bps.

Monetary policy, illiquid collateral and bank lending during the European sovereign debt crisis with J. Barthelemy, and V. Bignon, *Economics and statistics* (2017)

This paper assesses the effect on banks' lending activity of accepting illiquid collateral at the central bank refinancing facility in times of wholesale funding stress. Panel regression estimates show that the banks that pledged more illiquid collateral with the Eurosystem reduced less their lending to non-financial firms and households: a one standard deviation increase in the volume of illiquid collateral pledged corresponded to a 1.1 % increase in loans to the economy.

Euro-Area Quantitative Easing and Portfolio Rebalancing with Ralph S.J. Koijen, François Koulischer Motohiro Yogo *American Economic Review, Papers and proceedings* (May 2017).

We use new granular data on institutional investors portfolio holdings to assess the rebalancing channel at play in response to the ECB asset purchase program. In response to the program, foreign investors sold most of the purchase-eligible government bonds. Banks also sold purchase-eligible government bonds to a lesser extent, but insurance companies and pension funds bought them.

Policy notes and peer-reviewed short publications

A Tiering Rule to Balance the Impact of Negative Policy Rates on Banks with M. Girotti and J.G- Sahuc, *Finance Research Letter* (Sept 2021).

Negative interest rate policy makes excess liquidity costly to hold for banks and this may weaken the bank-based transmission of monetary policy. We design a rule-based tiering system for excess reserve remuneration that reduces the burden of negative rates on banks while ensuring that the central bank keeps control of interbank interest rates. Using euro-area data, we show that under the proposed tiering system, the aggregate cost of holding excess liquidity when the COVID-19 monetary stimulus fully unfolds would be more than 36% lower than that under the ECB's current system.

Working papers

Stablecoins and the financing of the real economy with J. Barthélémy and P. Gardin (Nov 2021, new version Oct 2022, submitted)

Stablecoins are crypto-assets that aim to maintain their value stable relative to a fiat currency. This paper documents one implication of their massive growth since 2020 for the financing of the real economy. The largest stablecoins manage their peg with the US dollar by holding short-term safe assets. We identify changes in the stablecoin demand for US dollar-denominated commercial papers (CP) by exploiting cross-sectional and time-varying heterogeneity in the main stablecoins' reserve assets policy. We show that CP issuers catered to the additional demand from stablecoins by issuing more, illustrating the implications of stablecoins for financial stability and the financing of the real economy.

Should we pay banks to lend? Evidence from the Eurosystem's TLTRO and the euro area credit registry with Emilie Da Silva, Vincent Grossmann-Wirth, and Miklos Vari (Nov 2021, submitted).

Since March 2020 the Eurosystem has provided subsidies to Euro-Area banks, via its Targeted Longer-Term Refinancing Operations (TLTRO). Under this program, banks can borrow from the Eurosystem at a rate as low as -1%, conditional on their lending to the real economy. This paper uses a simple theoretical model to disentangle between "targeted" and "profitability" channels. We test those channels on the new Euro-Area credit registry data (AnaCredit). To overcome reverse causality, we employ novel identification strategies based on TLTRO parameters set before the pandemic and unexpected changes afterwards. We find support for both channels and conclude the targeted channel is marginally stronger.

Assessing the dynamic effects of the ECB's Asset Purchase Programme with Stéphane Lhuissier (Mar 2021, submitted).

This paper estimates the dynamic effects of the ECB's asset purchase programme (APP) using a proxy structural vector autoregression. We construct our proxy for structural APP shocks as unexpected changes in the size of additional purchases announced by the ECB. Unexpected changes are inferred on the basis of public expectations released in quantitative surveys just before the monetary policy announcements. We find a shock to APP of one percent of GDP leads to a

maximum impact in industrial production and consumer prices by 0.15 percent and 0.06 percent, respectively. Our counterfactual analyses indicate inflation would have fallen into negative territory without December 2015 and March 2016 APP recalibrations.

Showing off cleaner hands: mandatory climate-related disclosure by financial institutions and the financing of fossil energy with Jean-Stéphane Mésonnier (Jan 2021, submitted)

We investigate the real effects of mandatory climate-related disclosure by financial institutions on the funding of carbon-intensive industries. A French law, first of its kind, came into force in January 2016 and requires institutional investors (i.e., insurers, pension funds and asset management firms), but not banks, to report annually on both their climate-related exposure and climate change mitigation policy. Using a unique dataset of security-level portfolio holdings, we find that investors subject to the new disclosure requirements curtailed their financing of fossil energy companies by some 40% compared to investors in the control group.

Price Impact of Bond Supply Shocks: Evidence from the Eurosystem’s Asset Purchase Program with W. Arrata, Banque de France Working Paper No. 623 (March 2017, permanent working paper)

We use new daily security-level data and test the impact of the Eurosystem’s Public sector purchase program (PSPP) on bond returns in the French bond market. We investigate three possible types of supply shocks: related to the cumulative past purchases (“stock”) since the start of the program, the transactions themselves on the day of the purchase (“flow”), and the variation in the expected total size of the program (“expected stock”). Our results show that having purchased 10% of a bond outstanding correlates with a decrease in yield of about -13 bps to -26 bps on average in the first year of implementation of the program, with bigger effects in the most illiquid segments. Set aside very particular conditions, we don’t find any significant supplemental effect from flows, presumably in line with the market neutrality objective of the Eurosystem.
